

Full-Stack Assessment: Product Discovery & Purchase Confidence

Context

LAAM is a marketplace for South Asian fashion. Customers often browse many similar-looking products across different brands, sizes, prices, delivery timelines, and stock availability.

A common user problem is:

“I like a product, but I am not fully confident whether it is available in my size, whether it can arrive on time, whether the price is final, or whether there are better alternatives.”

This lack of confidence can lead to drop-offs before add-to-cart or checkout.

Product Problem

Design and build a small full-stack experience that helps a customer make a confident purchase decision for a fashion product.

The solution should improve the customer's ability to answer questions like:

- Is this product available for me?
- Is my preferred size in stock?
- What will I actually pay?
- Can I trust the delivery promise?
- Are there similar alternatives if this product is not suitable?

You do **not** need to build a complete marketplace or checkout system. Focus on a small but meaningful slice of the experience.

Your Task

Define the scope, technical approach, and implementation yourself.

You should decide:

- What user flow to build
- What data model is needed

- What backend APIs are needed
- What frontend experience is needed
- What tradeoffs to make given the time limit
- What edge cases are important
- What you would defer and why

You may use mock data, in-memory storage, JSON files, SQLite, or any lightweight setup.

Time Limit

Please spend **3–4 hours maximum**.

We are not looking for a large polished product. We are looking for your judgment, prioritization, technical execution, and ability to make pragmatic tradeoffs.

AI Usage

You may use AI tools freely.

Please include a short note in your README explaining:

- What AI tools you used
- What parts AI helped with
- What you reviewed or changed manually
- One example where you corrected, rejected, or improved AI output
- When you start using AI, ask it to build an audit trail of all activities.

Deliverables

Submit a working project with:

- Source code
- Instructions to run locally
- A README with the content described below
- Any tests you were able to add
- Notes on tradeoffs and future improvements
- Audit trail of all AI driven activities.

README Expectations

Your README should include:

1. Problem Understanding

Briefly explain how you interpreted the product problem and what specific user pain point you chose to solve.

2. Scope

Explain what you built and what you intentionally did not build.

3. User Flow

Describe the main user flow. For example:

- How a customer discovers the product
- How they check availability, size, price, or delivery information
- How they decide whether to proceed or consider alternatives

4. Technical Approach

Explain:

- Frontend structure
- Backend/API structure
- Data model
- Key technical decisions
- Any important assumptions

5. How to Run

Include clear instructions to run the project locally.

6. Tests

Mention any tests you added.

If you were not able to add tests within the time limit, explain what you would test first and why.

7. Tradeoffs

Explain the tradeoffs you made because of the 3–4 hour time limit.

8. Future Improvements

Explain what you would improve if this were going to production.

9. AI Usage

Explain:

- What AI tools you used
- What AI helped generate or reason through
- What you manually reviewed or changed
- One example where you corrected, rejected, or improved AI output

What We Will Evaluate

We will evaluate your submission based on:

- How clearly you understood and scoped the product problem
- Whether your solution addresses a real customer pain point
- Quality of the user experience
- Quality of technical decisions
- Backend and frontend design
- Handling of edge cases
- Code readability and maintainability
- Practicality of tradeoffs
- Quality of the README and explanation
- How effectively and responsibly you used AI

Follow-Up Discussion

- We may schedule a follow-up discussion session if necessary.
